

Creates a WSD port and adds a local IPP/IPPS printer when a IP address (or DNS name) to the printer is provided. This utility allows for either encrypted (IPPS) or unencrypted (IPP) service.

Example - Add a single IPP printer to the workstation

```
AddIppPrinter /p=ww.xx.yy.zz /s=<ipp, ipps, or ipps_443>
```

Where ww.xx.yy.zz is the IP address of a printer that has active IPP service. Note: the printer's name will be derived from the IPP printer itself, you have no control of this initially. However, you can change this once it is installed on your machine.

Where /s=ipp for IPP service or ipps for IPPS service. These are standard choices on Windows. Alternately, you can use ipps_443 if the firewall blocks 631 (but allows https) and the printer supports this,

Example - Add multiple IPP printers to the workstation

```
AddIppPrinter /l=C:\Temp\IppPrinterList.txt /s=ipp
```

Where C:\Temp\IppPrinterList.txt is a file with a list of IP addresses corresponding to IPP printers. The file should be formatted with one IP address per line. In this example (/s=631) IPP is used instead of IPPS.

Notice: The IPP printer creation will fail if the IP address corresponds to an existing WSD port on the workstation.
